**Observer Pattern**

The **Observer Pattern** defines a one-to-many dependency between objects so that when one object changes state, all of its dependents are notified and updated automatically.

Toni Sellarès

**OO Design Principle**

*Strive for loosely coupled designs between objects that interact.*

Loosely coupled designs allow us to build flexible OO systems that can handle changes because they minimize the interdependency between objects.
The Weather-O-Rama!

The Job: Create an app that uses the `WeatherData` object to update three displays for current conditions, weather stats, and a forecast.

The WeatherData class

These three methods return the most recent weather measurements for temperature, humidity, and pressure respectively.

We don’t care HOW these variables are set; the `WeatherData` object knows how to get updated information from the Weather Station.

```java
public void measurementsChanged () {
    // Your code goes here
}
```

A clue: what we need to add!
The Specs so far

- The `WeatherData` class has getter methods for three measurement values: `temperature`, `humidity`, and `pressure`.

- The `measurementsChanged()` method is called anytime new weather measurement data is available (we don’t know or care how this method is called; we just know that it is).

- We need to implement three display elements that use the weather data: a `current conditions` display, a `statistics` display, and a `forecast` display. These displays must be updated each time `WeatherData` has new measurements.

- The system must be expandable - other developers can create new custom display elements and users can add or remove as many display elements as they want to the application.

A First Misguided Attempt at the Weather Station

```java
public class WeatherData {
    // instance variable declarations

    public void measurementsChanged() {
        float temp = getTemperature();
        float humidity = getHumidity();
        float pressure = getPressure();

        currentConditionsDisplay.update(temp, humidity, pressure);
        statisticsDisplay.update(temp, humidity, pressure);
        forecastDisplay.update(temp, humidity, pressure);
    }
    // other WeatherData methods here
}
```

Grab the most recent measurements by calling the `WeatherData`'s getter methods (already implemented)

Now update the displays.
Call each display element to update its display, passing it the most recent measurements.
What’s wrong with the first implementation?

By coding to concrete implementations we have no way to add or remove other display elements without making changes to the program.

At least we seem to be using a common interface to talk to the display elements...they all have an update( ) method that takes temp, humidity and pressure values.

Area of change, we need to encapsulate this.

Time for the Observer!

- The Newspaper or Magazine subscription model:
  - A newspaper publisher goes into business and begins publishing newspapers.
  - You subscribe to a particular newspaper, and every time there is a new edition, its gets delivered to you. As long as you remain a subscriber, you get new newspapers.
  - You unsubscribe when you don’t want the newspapers anymore -- and they stop being delivered.
  - While the publisher remains in business people, hotels, airlines etc constantly subscribe and unsubscribe to the newspaper.
The Observer Pattern Defined

The **Observer Pattern** defines a one-to-many dependency between objects so that when one object (subject) changes state, all of its dependents (observers) are notified and updated automatically.

- Some observers may observe more than one subject (many-to-many relation).
- The update should specify which subject changed.

**Motivation:**

- A common side-effect of partitioning a system into a collection of cooperating classes is the need to maintain consistency between related objects.
- You don’t want to achieve consistency by making the classes tightly coupled, because that reduces their reusability.
Observer Class Diagram

Objects use Subject interface to register as observers and also to remove themselves from being observers.

Each subject can have many observers. All potential observers need to implement the Observer interface. This interface has just one method, update(), that gets called when the Subject's state changes.

Concrete observers can be any class that implements the Observer interface. Each observer registers with a concrete subject to receive updates.

A concrete subject always implements the Subject interface. In addition to the register (attach) and remove (detach) methods, the concrete subject implements a notify() method to notify observers whenever state changes.

Observer pattern: Structural Code

```java
/**
 * Maintains a reference to a ConcreteSubject object. Stores state that should stay consistent with the subject's.
 * Implements the Observer updating interface to keep its state consistent with the subject's.
 */

public class Test{
    public static void main( String arg[] ){
        Subject subject = new ConcreteSubject();
        Observer observer = new ConcreteObserver();
        subject.attach( observer );
        subject.notify();
    }
}
```
import java.util.Vector;
/**
 * Knows its observers. Any number of Observer objects may observe a subject.
 */
public class Subject{
    private Vector observers = new Vector();
    public void attach( Observer observer ){
        if( observers.contains( observer ) == false )
            observers.addElement( observer );
    }
    public boolean detach( Observer observer ){
        return observers.removeElement( observer );
    }
    public void notifyObservers(){
        // Synchronous update. Beware, this mechanism will block as each
        // observer is updated. Depending on how sensitive your code is to
        // blocking, you may want to kick-off a thread for each observer that
        // requires notification and then wait for all threads to complete.
        for( int i = 0; i < observers.size(); ++i ){
            Observer observer = (Observer) observers.elementAt(i);
            observer.update();
        }
    }
}

/**
 * Defines an updating interface for objects that should
 * be notified of changes in a subject.
 */
public interface Observer{
    void update();
}

/**
 * Stores state fo interest to ConcreteObserver objects. Sends
 * a notification to its observers when its state change.
 */
public class ConcreteSubject extends Subject {
    public int getState() { return 1; }
}

/**
 * Maintains a reference to a ConcreteSubject object. Stores state that should
 * stay consistent with the subject's. Implements the Observer updating
 * interface to keep its state consistent with the subject's.
 */
public class ConcreteObserver implements Observer {
    public void update() { System.out.println( "update() called." ); }
}
Design choices

- When to notify Observers:
  - automatic on each change
  - triggered by client

- How to communicate information about the change:
  - push: subject gives details to observers
  - pull: subject notifies only that a change has occurred, observer queries subject about details

Summary

- Subject(s) update Observers using a common interface.

- Observers are loosely coupled in that Subject(s) knows nothing about them, other than they implement the Observer interface.

- Don’t depend on a specific order of notification for your Observers.
Designing the Weather Station

All weather components implement the Observer interface. This gives the subject a common interface to talk to when it comes time to update.

Create an interface for all display elements to implement. The display elements just need to implement a display ( ) method.

Subject interface

observers

Subject interface

observers

Observer

update ( )

display ( ) { // display current measurements }

DisplayElement

display ( )

CurrentConditions

update ( )

display ( ) { // display current measurements }

ForecastDisplay

update ( )

display ( ) { // display the forecast }

StatisticsDisplay

update ( )

display ( ) { // display avg, min, and max measurements }

WeatherData now implements the Subject interface.

Implementing the Weather Station

public interface Subject {
    public void registerObserver (Observer o);
    public void removeObserver (Observer o);
    public void notifyObservers ( );
}

public interface Observer {
    public void update (float temp, float humidity, float pressure);
}

public interface DisplayElement {
    public void display ( );
}

Both of these methods take an Observer as an argument, that is the Observer to be registered or removed.

This method is called to notify all observers when the Subject's state has changed.

The Observer interface is implemented by all observers, so they all have to implement the update ( ) method.

These are the state values the Observers get from the Subject when a weather measurement changes.

The DisplayElement interface just includes one method, display ( ), that we will call when the display element needs to be displayed.
Implementing the Subject Interface in WeatherData

```java
public class WeatherData implements Subject {
    private ArrayList observers;
    private float temperature;
    private float humidity;
    private float pressure;

    public WeatherData() {
        observers = new ArrayList();
    }
    public void registerObserver(Observer o) {
        observers.add(o);
    }
    public void removeObserver(Observer o) {
        int j = observer.indexOf(o);
        if (j >= 0) {
            observers.remove(j);
        }
    }
    public void notifyObservers() {
        for (int j = 0; j < observers.size(); j++) {
            Observer observer = (Observer) observers.get(j);
            observer.update(temperature, humidity, pressure);
        }
    }
    public void measurementsChanged() {
        notifyObservers();
    }
    // add a set method for testing + other methods.
}
```

Added an ArrayList to hold the Observers, and we create it in the constructor.

Here we implement the Subject Interface.

Notify the observers when measurements change.

The Display Elements

```java
public class CurrentConditionsDisplay implements Observer, DisplayElement {
    private float temperature;
    private float humidity;
    private Subject weatherData;

    public CurrentConditionsDisplay(Subject weatherData) {
        this.weatherData = weatherData;
        weatherData.registerObserver(this);
    }
    public void update(float temperature, float humidity, float pressure) {
        this.temperature = temperature;
        this.humidity = humidity;
        display();
    }
    public void display() {
        System.out.println("Current conditions : "+ temperature + " F degrees and "+ humidity + " % humidity");
    }
}
```

Implements the Observer and DisplayElement interfaces.

The constructors passed the weatherData object (the subject) and we use it to register the display as an observer.

When update() is called, we save the temp and humidity and call display().

The display() method just prints out the most recent temp and humidity.
